SECTION I--GENERAL INFORMATION

1.1 SCOPE

This manual contains information useful in the installation and operation of Tandon Corporation's TM600 family of 5.25" rigid disk drives. This manual also contains interface requirements and descriptions of signals. TM600 refers to Model Numbers TM602S, TM603S, and TM603SE, as appropriate.

1.2 INTRODUCTION

The TM600 family of 5.25" rigid disk drives are low-cost, random access memories that use moving head, noncontact recording techniques. There are both two- and three-platter models, which use standard Winchester technology and 130 millimeter rigid media.

This drive consists of storage media that is contained within the drive in a fixed (nonoperator removable) configuration, read/write and control electronics, the drive mechanism, a read/write head, a precision split band positioning device, and an air filtration system.

Interface flexibility is provided by using an industry standard interface on the drive. The "S" version is compatible with larger capacity disk drives. Compatible is defined as using the same pin assignment where the signal and the function are common.

1.3 DISK DRIVE PERFORMANCE CHARACTERISTICS

The information contained in Table 1 pertains to all models of the Tandon TM600 family of disk drives.

1.4 DISK DRIVE MODEL SPECIFICATIONS

Table 2 contains a list of the drive models available and the number of platters each one has.

1.5 PHYSICAL DIMENSIONS

The major physical dimensions of the TM600 family of drives are contained in Figure 2. These dimensions are given in English and in metric units.

Figure 2
Disk Drive Physical Dimensions

SECTION II--INSPECTION, INSTALLATION, AND INTERFACES

2.1 INTRODUCTION

This section contains information pertinent to the inspection, installation, and interfaces of the Tandon TM600 family of rigid disk drives.

The electrical interface between the drive and the host system is via four connectors. J1 provides control signals for the drive. J2 provides for the radial connection of read/write data signals. J3 provides for D. C. power. J4 provides for frame ground. Figure 3 contains the locations of the interface connectors.

2.2 UNPACKING AND INSPECTION

The drive is shipped in a protective container which, when bulk packaged, minimizes the possibility of damage during shipment. The following procedure is the recommended method of uncrating the drive.

1. Place the shipping container on a flat work surface.
2. Remove the upper half of the inner container.
3. Remove the drive from the lower half of the inner container.
4. Check the model number and top assembly description against the packing slip.
5. Visually examine the contents of the shipping container for possible damage.
6. Notify the carrier immediately if any damage is found.
7. The inside chamber of the drive is a sealed compartment that must not be opened.

NOTE

REMOVAL OF THE COVER OF THE DRIVE
INVALIDATES THE WARRANTY.

Figure 3
Locations of Interface Connectors

Before applying power to the disk drive, the following inspection procedure should be performed:

1. Check to ensure that the circuit boards are secure.
2. Check to ensure that the connectors are firmly seated.
3. Notify the carrier immediately if you find any damage.

2.3 MOUNTING CHARACTERISTICS

The mounting characteristics of the TM600 family of disk drives are contained in Figure 2. There are four 6-32, tapped mounting holes on the bottom of the disk drive, and two on each side of it.

2.4 POWER CABLING

The D.C. power connector, J3, is a four-pin AMP Mate-N-Lok device, P/N 350211-1, which is mounted on the solder side of the circuit board. The recommended mating connector, P3, is AMP P/N 1-480424-0, using AMP pins P/N 60617-4. J3 pins are labeled on the J3 connector. Figure 4 contains an illustration of the J3 connector.

Figure 4

J3 Connector

The frame ground connector, J4 is the Faston AMP P/N 61761-2. The recommended mating connector is AMP P/N 62187-1.

2.5 STANDARD INTERFACE

The standard or "S" model interface is contained in Table 2-1. Connection to J1 is via a 34-pin circuit board edge connector. The dimensions of the J1 connector are found in Figure 5. The pins are numbered 1 through 34. The even numbered pins are located on the component side of the circuit board. Pin 2 located on the end of the circuit board connector closest to the D. C. power connector J3/P3, and it is labeled. A key slot is located between Pins 4 and 6.

Figure 5
J1 Connector Dimensions

Figure 6
J2 Connector Dimensions

The recommended mating connector for P1 is a 3M ribbon connector, P/N 3463-0001, without ears.

Connection to J2 is via a 20-pin circuit board edge connector. The dimensions of the J2 connector are found in Figure 6. The pins are numbered 1 through 20. The even numbered pins are located on the component side of the circuit board. The recommended mating connector for P2 is a 3M ribbon connector, P/N 3461-0001, without ears. A key slot is located between Pins 4 and 6.

SECTION III--THEORY OF OPERATION

3.1 INTRODUCTION

There are three kinds of interface signals:

1. Input Control Lines
2. Output Control Lines
3. Data Transfer Lines

Signals on the Input Control lines are standard TTL levels. They have the following electrical specifications:

True: 0.0 volt D. C. to 0.4 volt D. C. @ $I = 40$ mA maximum

False: 2.5 volt D. C. to 5.25 volt D. C. @ $I = 0$ mA open

See Figure 7 for the recommended circuit.

Figure 7

Control Signal Driver/Receiver Circuit Combination

3.2 INPUT CONTROL LINES

There are two kinds of Input Control lines, those that are multiplexed in a multiple drive system and those that do the multiplexing.

The Input Control lines that are multiplexed include:

1. Reduced Write Current
2. Write Gate
3. Head Select
4. Step Interface
5. Direction In

The Input Control lines that do the multiplexing are:

1. Drive Select 0
2. Drive Select 1
3. Drive Select 2
4. Drive Select 3

3.2.1 Reduced Write Current

When this Input Control line is activated low (true) in conjunction with the write gate, a lower value of write current is selected for writing on the disk. When the signal is set high (false), the higher value write current is selected. When writing on Tracks 0 through 127, it is recommended that this line be set false. For Tracks 128 and greater, the Reduced Write Current line should be set true.

A 220/230 ohm resistor pack allows the line to be terminated.

3.2.2 Write Gate

The Write Gate signal enables data to be written on the disk when it is activated or when the logical zero (true) level is reached. The ready line must be valid before write gate is activated. If a disk drive fault occurs, further writing on the disk is prohibited. In addition, the Seek Complete line should go true before you begin to write any information on the disk.

The inactive or logical high (false) level on the Write Gate line enables the step pulses to step the head arm actuator.

3.2.3 Head Select

There are three Head Select lines. They are used to select each read/write head--0, 1, or 2--in a binary coded sequence.

Head Select signals are logic low (true) levels. They must be activated in conjunction with the Drive Select lines. The heads are numbered 0 through 5. Head Select 0 is the least significant line. Table 3-1 contains information about the Head Select line sequence, disk drive model number, and numbers that may be selected.

Table 3-1

Head Select

Head Select Line Sequence			Model Number	
2 ²	2 ¹	2 ⁰	TM602	TM603
			Head Number	Selected
1	1	1	0	0
1	1	0	1	1
1	0	1	2	2
1	0	0	3	3
0	1	1		4
0	1	0		5

Legend: 1 = Logical High (False)
 0 = Logical Low (True)

A 220/330 ohm resistor pack allows the line to be terminated.

3.2.4 Step Interface

When the Step Interface line is activated in conjunction with the Direction In line, the read/write heads move in the direction defined by the Direction In line. The motion is initiated by a logical zero to a logical one transition or by the trailing edge of the step pulse. Any change in the Direction In line must be made one hundred nanoseconds before the leading edge of the step pulse. The quiescent state of this line should be held logically high (false).

The heads move at the rate of the incoming step pulses. Figure 8 contains the sequence and the requirements for step timing.

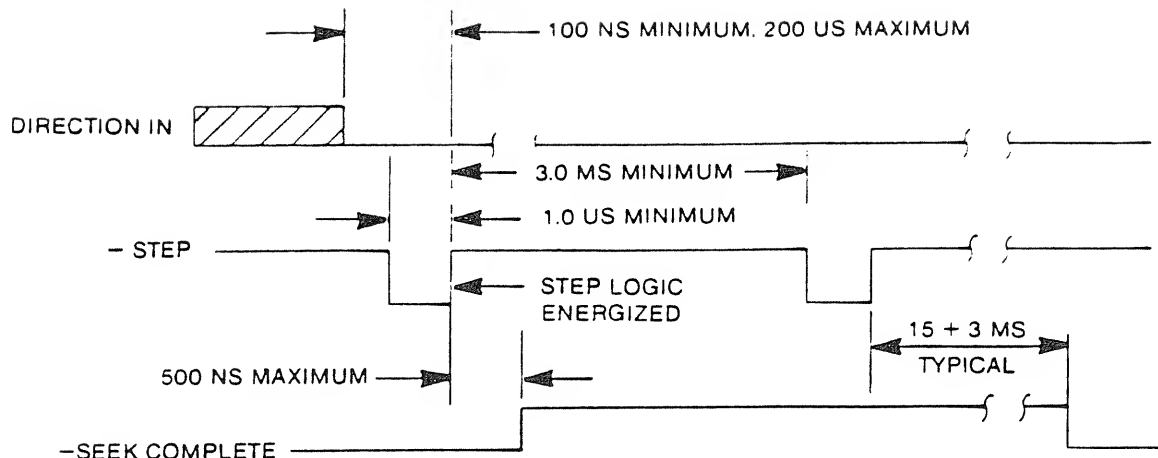

Figure 8

Step Mode Timing Diagram

3.2.5 Direction In

The Direction In line determines the motion of the read/write heads when a step pulse is issued. The motion is toward the center of the disk if the Direction In line is in the true (low) state when a step pulse occurs. The direction of the motion is away from the center of the disk if the Direction In line is in the false (high) state when a step pulse occurs.

A 220/330 ohm resistor pack allows the line to be terminated.

3.2.6 Drive Select

Drive Select lines 0 through 3 provide a means of selecting and deselecting a drive. These four lines select one of four drives that are daisy chained to the controller.

The drive address is determined by a select shunt on the Signal circuit board. Drive Select lines 0 through 3 provide a means of daisy changing a maximum of four drives to a controller.

When logically high (false), the output drivers are open circuits or logically high (false), and the drive receivers do not acknowledge signals presented to them. A Drive Select line must remain stable in the true (low) state until a Step or Read/Write command is executed.

Only one line can be true (low) at a time. An undefined operation might result if two or more units are assigned the same address or if two or more Drive Select lines are in the true (low) state simultaneously.

3.3 OUTPUT CONTROL LINES

The Output Control lines are enabled by their respective Drive Select line. They send status information to the controller, such as: drive selected, seek complete, Track000 fault, and line ready. In addition, the Index line is provided as an output to the controller for timing information.

The Output Control lines use an open collector gate that is capable of sinking a maximum of forty milliamperes in a logical low (true) level, with a maximum voltage of 0.4 volt measured at the driver. When the gate is off or logically high (false), the collector cutoff is a maximum of 250 u amps. See Figure 8 for the recommended circuit.

3.3.1 Drive Selected

When the Drive Selected lines coincide with the selected jumper on the shunt pack, the Select Status line goes logically low (true). This line informs the host system of the selection status of the drive.

NOTE

ONLY ONE DRIVE MAY BE SELECTED AT A TIME.

3.3.2 Seek Complete

The Seek Complete line indicates that the read/write heads have settled on the selected track at the end of a seek sequence. This status line is set logically zero (true) at the end of a normal seek. It is set logically high (false) in two cases:

1. A recalibration sequence is initiated by drive logic at power on because the heads are not over Track 000.
2. Five hundred nanoseconds, typical, after the leading edge of a step pulse or of a series of step pulses.

3.3.3 Track 000

The Track 000 line indicates to the host system that the read/write heads are positioned on Track 000. The Track 000 line goes logically low (true) only when the heads are positioned on Track 000. It remains low until the heads are moved away from Track 000, the outermost data track.

3.3.4 Fault

The Fault line indicates to the host system that a condition exists on the disk drive that is going to cause improper writing on the disk. When this line is logically low (true), Write Data is inhibited and further writing on the disk is prohibited until the condition is corrected. The condition under which the Fault line goes true is that D.C. voltages are grossly out of tolerance.

3.3.5 Line Ready

In conjunction with the Seek Complete line, the Line Ready line indicates to the host system that the disk drive can read, write or seek, and that all I/O signals are valid. The Line Ready line goes logically low (true) approximately 15 seconds after power on. The Line Ready line goes logically high (false) if the drive is not selected or if the speed of the motor is too slow. When this line is false, all writing and seeking is inhibited.

3.3.6 Index

An index pulse is provided once every revolution (16.67 ms nominal) to indicate the beginning of a track to the controller. The transition from logically high (false) to logically low (true) is the only valid transition. The leading edge of the pulse must be used to ensure accurate timing.

3.4 DATA TRANSFER LINES

The Data Transfer lines transfer information between the host system and the disk drive when the drive is selected. These lines are differential in nature. They may be multiplexed when using Drive Select.

The MFM Write Data pair of lines and the MFM Read Data pair of lines are provided for the transfer of data. Figure 9 contains a typical driver/receiver circuit combination used for data transfer signals.

3.4.1 MFM Write Data

The MFM Write Data lines are the differential pair that provide the data to be stored on the track. A flux reversal on the track to be written is caused when the plus (+) MFM

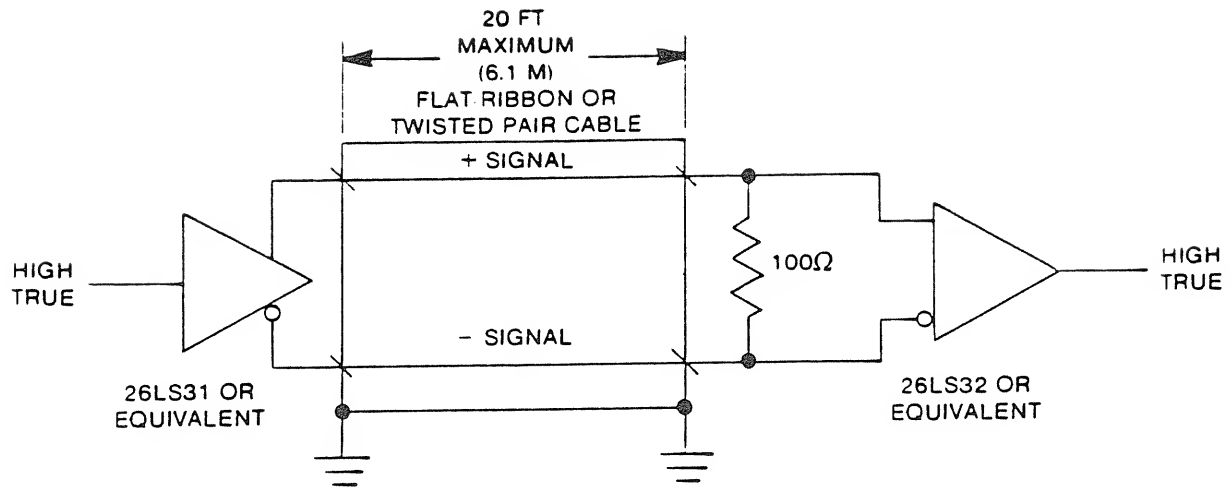

Figure 9

Data Line Driver/Receiver Circuit

Write Data line goes more positive than the minus (-) MFM Write Data line, provided that the Write Data line is logically low (true). When the disk drive is in a Read mode, the host system must ensure that the MFM write data signals are in the inactive state. The inactive state can be attained by making the plus MFM Write Data line more negative than the minus MFM Write Data line.

3.4.2 MFM Read Data

These lines are a differential pair that recover the data previously written on a track. A flux reversal on the track to be read is caused when the plus MFM Read Data line goes more positive than the minus MFM Read Data line. Subsequently, the differential pair signal is transmitted to the host system via the MFM Read Data lines.

APPENDIX A
CUSTOMER INFORMATION BULLETINS

CUSTOMER INFORMATION BULLETIN

TM600 RIGID DISK DRIVE

RAMPED SEEK MODE

Tandon uses a Customer Information Bulletin to inform our customers of changes in and improvements to our products. The following information is an option on the Tandon TM600 family of rigid disk drives that may be of interest in your application.

Our current drives are designed to operate at a minimum time between steps of three (3) milliseconds. Given eighteen (18) milliseconds for last step and settling time, this step rate results in an average seek time of 170 milliseconds for the 153 cylinder drive.

Customer requirements may necessitate a reduction in average seek time. By using the ramped seek mode and giving correct step pulse timing, the present drive's average access time can be improved.

A. In order to use a ramped seek, four major conditions must be met:

1. The drive must have a Control and Data circuit board, P/N 187045-001.
2. The Pins 8 and 9 programming shunt of the Control and Data circuit board must be closed (shorted).
3. The viscous damper must be mounted to the stepper motor.
4. The controller must issue step pulses in accordance with the algorithm below. Note that two pulses per track are required in ramped seek.

B. The pulse timing for single-track to nine-track seek is:

Two pulses separated by 1.5 milliseconds for each track, i.e., a one-track seek is equal to two pulses, a nine-track seek is equal to fourteen pulses.

C. Pulse timing for an 10 track seek or greater.

1. Acceleration Phase:

2. Slew Phase: two pulses separated by .75 milliseconds for each track.

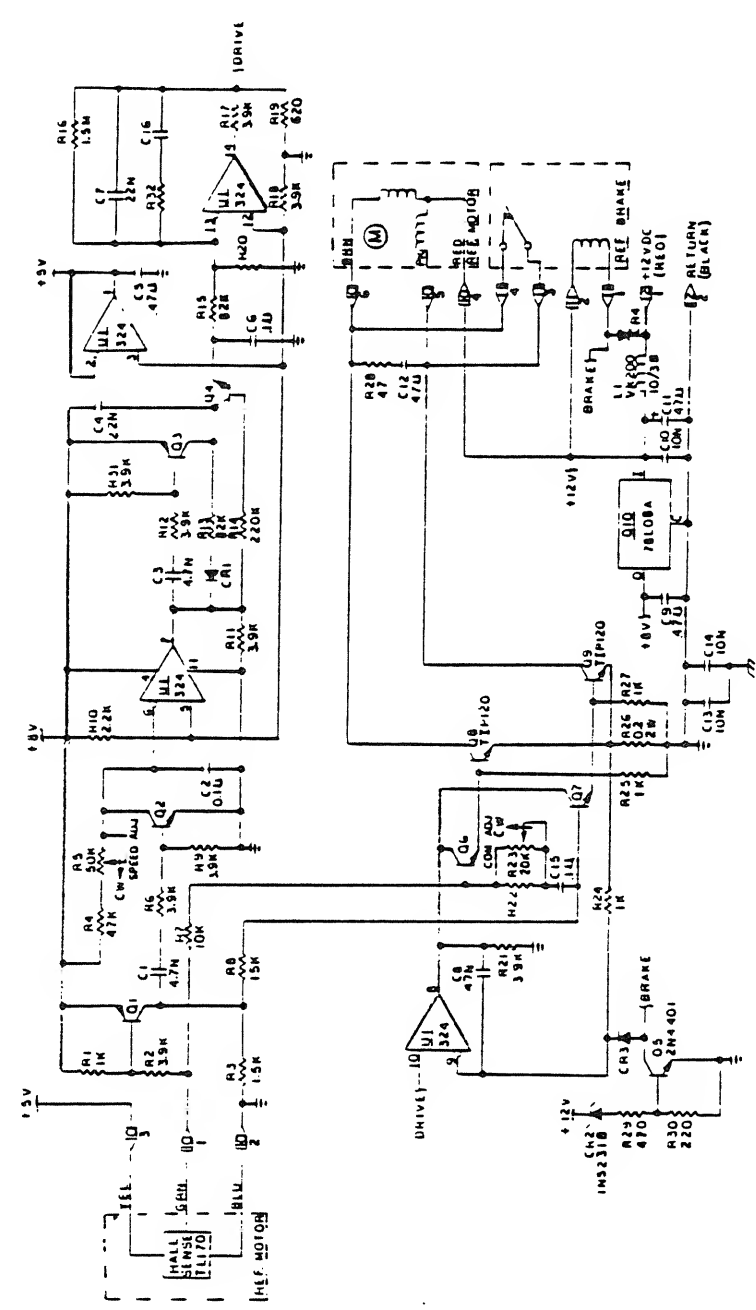

3. Deceleration Phase: last two tracks or seek.

If you have any questions or need additional information, please do not hesitate to contact me.
